Abstract

Convulsive Syncope can be difficult to distinguish from seizures at times. We present a young adult with cardiogenic convulsive syncope that mimic seizures. Continuous cardiac monitoring revealed various arrhythmias during seizure like activity. She had a viral prodrome. Cardiac MRI was diagnostic for myocarditis. More detailed studies for the role of a noninvasive cardiac testing such as Cardiac MRI (CMR) and newer treatment modalities such as anti-thymocyte immunoglobulin are required for the management of Viral Myocarditis.

Case report: A 32-year-old female was brought to the Emergency Department after a cardiac arrest at work. She was found to be pulseless, so three rounds of CPR were performed, and four shocks were delivered. Return of spontaneous circulation was achieved. She reverted to full consciousness spontaneously within minutes without confusion or cognitive deficits. On further enquiry she admitted a one-week history of fever and cough. She was evaluated in an Urgent care center and sent home on Pseudoephedrine.

Introduction

Differentiating Cardiovascular Convulsive syncope from Seizure has always been a dilemma [1,2]. We describe a case of a previously healthy young woman presenting with a sudden onset of intractable Stokes Adam Attack. Vasovagal syncope is the most likely etiology of syncope in young women [1]. However detailed history taking in our patient revealed a prodrome of viral illness. Later found to have myocarditis on cardiac MRI. Myocarditis can have variable presentation [1,3]. This case depicts life threatening arrhythmias that present as seizure like episodes. The arrhythmias caused as a sequela of myocarditis.
showed mildly dilated left atrium and left ventricle with reduced left ventricular ejection fraction (Figure 5 and Figure 6).

She was overdrive paced for a day (Figure 7). On telemonitoring, Rhythm was sinus rhythm with PVC. IV Amiodarone was also given to control ventricular arrhythmias.

On day 2, TVP was removed and patient was transferred to a tertiary care center for a cardiac MRI. Cardiac MRI revealed Global myocardial SI increase in T2-weighted images and increased global myocardial early gadolinium enhancement ratio between myocardiun and skeletal muscle in gadolinium-enhanced T1-weighted image. A Subcutaneous Implantable Cardioverter Defibrillator (ICD) was placed for secondary prevention of arrhythmias. Patient was discharged with close follow up.

**Discussion**

This case describes a patient with classic Stokes Adam attack associated with a myriad of ventricular arrhythmias in the setting of viral myocarditis.

Differentiating syncope from seizures can be difficult at times [1,2]. The Stokes-Adams attack, a form...
Our patient exhibited generalized jerking and myoclonic movements on presentation. The loss of muscle tone (atonia) resulting in sudden collapse, the absence of post ictal phase, prompt return of consciousness favors syncope over seizure in our patient [1,2].

of cardiovascular syncope, classically described as an abrupt, transient loss of consciousness due to a sudden but pronounced decrease in the cardiac output, which is caused by a paroxysmal shift in the mechanism of the heart beat [4].
Carditis/Bacterial superinfections [3]. Unfortunately, we do not have any predictive methods to triage these patients on initial presentation at urgent care centers.

Conclusion

Literature reveals various presentations of Stokes Adams Attack. A myriad of arrhythmias are associated with it. AV blocks are more commonly associated than Ventricular arrhythmias [4,7]. This case emphasizes the importance of thorough history from multiple available sources because intractable Stokes Adams can mask an underlying heart conditions such as infection.

Treatment of myocarditis consists of both specific therapy aimed at the cause of the myocarditis and supportive treatment to control Heart failure and arrhythmias [3,5,6]. The Heart Failure Society of America 2010 comprehensive heart failure practice guideline recommends considering endomyocardial biopsy for patients with acute deterioration of heart function of unknown origin that is not responding to medical treatment [6].

It is a common case scenario where patients are dismissed from urgent care centers with common cold remedies to have to return with life threatening Myocardiitis/Bacterial superinfections [3]. Unfortunately, we do not have any predictive methods to triage these patients on initial presentation at urgent care centers.
Cardiovascular magnetic resonance (CMR) has become the primary tool for noninvasive assessment of myocardial inflammation in patients with suspected myocarditis. The International Consensus Group on CMR Diagnosis of Myocarditis provides CMR protocol standards, terminology for reporting CMR findings, and diagnostic CMR criteria for myocarditis (i.e., “Lake Louise Criteria”) [8].

Current standard treatment of viral myocarditis is supportive care, although immunomodulatory therapies, such as steroids and intravenous immunoglobulin, are often used [6,9]. A systematic review concluded that there are insufficient data from methodologically strong studies to recommend routine IVIG therapy in patients with acute myocarditis. However, there are no controlled randomized data on IVIG in pediatric or adult patients with acute or chronic myocarditis or Dilated cardiomyopathy with biopsy-proven viral or autoreactive myocardial inflammation [9].
