Abstract

Objectives: The aim of this study was to assess the cerebral blood flow velocity using transcranial Doppler (TCD) ultrasonography in patients with Rheumatoid Arthritis (RA).

Materials and methods: A total of 22 patients aged 20 to 40-years-old with RA were enrolled in the RA group consecutively. Control group (non-RA group) consisted of 22 age and sex-matched, randomly selected patients without RA who had other diagnosis such as fibromyalgia and did not have risk factors for atherosclerosis (AS). Bilateral middle cerebral artery (MCA) peak-systolic, end-diastolic, and mean blood flow velocities, Pourcelot’s resistance index values and Gosling’s pulsatility index values were recorded with TCD by a neurosonologist blinded to RA and control groups.

Results: There were 22 people in each group. There were 10 women and 12 men in RA group. Therefore, control group was selected similar. The mean age was 38.6 in the RA group and 37.8 in the control group. Cerebral blood flow velocities of bilateral MCA were significantly higher in RA group than the control group.

Conclusions: Our study highlights the increased cerebral blood flow is indirectly associated with AS regarding persistent inflammation in patients with RA.

Introduction

Nowadays, Rheumatoid Arthritis (RA) is known to be associated with cardiovascular diseases. However, the subject of risk factor that rheumatoid arthritis for cerebrovascular diseases is controversial. There has been recently considerable attention about the possible role of systemic inflammation in the development of atherosclerosis (AS) in patients with rheumatic diseases [1]. Increased risk of AS regarding cardiovascular events such as myocardial infarction and stroke leads to a significantly increased mortality in patients with RA [2,3]. The aim of this study was to assess the cerebral blood flow velocity using transcranial Doppler (TCD) ultrasonography in patients with RA.

Patients and Methods

A total of 22 consecutively admitted patients aged 20 to 50-year-old with a principal diagnosis of RA. The non-RA control group consisted of 22 age- and sex-matched, randomly selected patients who not have any risk factors for AS such as diabetes, hypertension, and coronary artery disease. The erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) levels were measured to show the existence of inflammation. Consent was obtained from the local ethics committee, and all participants gave formal consent.

Examination of TCD ultrasonography was performed with Multi-Dop X DWL, TCD machine after the subjects rested in a supine position for 10 min. The right and the left MCA were insonated from the temporal windows at 50-65 mm depth three times (for different depths) with 2 MHz pulsed Doppler probes. Bilateral middle cerebral artery (MCA) peak-systolic, end-diastolic, and mean blood flow velocities, Pourcelot’s resistance index (RI) values and Gosling’s pulsatility index (PI) values were recorded with TCD by a neurosonologist blinded to RA and control groups.

Statistical Analysis

The data was analyzed using the Statistical Package for Social Sciences (SPSS Inc, Chicago, IL, USA) 15.0 program. Paired t-test, cross-tabs tests were used for statistical analysis, P < 0.05 was considered significant.
Discussion

The occurrence of nervous system manifestations in RA is rare. Inflammation plays an important role in the pathogenesis and progression of AS in patients with RA [4]. In RA group, we found that the mean values of ESR and CRP were higher than normal range. RA patients have higher levels of inflammatory markers, such as interleukin 6, tumor necrosis factor alpha, and CRP [5].

Rheumatic patients have been reported to show early features of AS such as an increase in intima media thickness in the carotid arteries and arterial stiffness [6]. Carotid-femoral pulse wave velocity was used as an indicator of arterial stiffness, whereas intima media thickness in the carotid arteries was used to evaluate preclinical atherosclerosis [6]. We attempted to evaluate the cerebral blood flow velocities with using TCD ultrasonography in patients with RA because increased cerebral blood flow velocities are indirectly associated with an increase in AS.

We found peak-systolic, end-diastolic, and mean blood flow velocities were significantly higher in RA group than the non-RA control group. But PI and RI values were not significantly different in each group. However, correct interpretation of PI, because it depends not only on cerebrovascular resistance, but also on several systemic and cerebral variables [7]. The mechanisms that underlie this condition (increased velocity but normal PI values) are most likely to be due to mild diffuse AS or low disease activity is not associated with accelerated AS [8]. The Rotterdam study reported that increased mild to moderate cerebral blood flow velocity is due to diffuse AS or vasoconstriction [9]. This study had methodological limitations, including inadequate sample size and evaluation of activity and damage like joint restriction.

Our study highlights the increased cerebral blood flow is indirectly associated with AS regarding persistent inflammation in patients with RA.
