This is a widefield colour fundus photograph of the right eye of an 83-year-old patient with wet AMD. The image shows extensive subretinal haemorrhage involving the macula and extending superiorly and inferiorly with serous retinal detachment inferiorly as a complication of wet AMD. Best corrected visual acuity dropped from 6/9 to HM. The patient underwent Intravitreal injection of Tissue plasminogen activator (tPA), ranibizumab and C3F8 gas to displace the blood from the macula (Figure 1).
