Abstract

Purpose: To investigate whether the application of a novel product containing a mix of osmoprotectant soluble molecules can modify tear osmolarity, clinical signs and subjective symptoms in dry eye patients.

Methods: Thirty patients (24 women, 6 men, median age 45.5 yrs) were enrolled. Inclusion criteria were: age ≥ 18 years, good general health, ocular discomfort symptoms for over three months, Ocular Surface Disease Index (OSDI) score ranging from 18 to 36, Schirmer test > 10 mm/5 min, Tear Film Break Up Time (TBUT) < 10 sec, corneal fluorescein staining ranging from from 1 to 7 according to NEI level. Patients were administered three times daily for a two-month period with Isomar Eyes Plus, a hypotonic solution containing Hyaluronic Acid, Hypromellose and L-Carnitine, erythrol and betaine as osmoprotectant soluble molecules. Tear osmolarity (TearLab), Schirmer I Test, corneal and conjunctival vital stainings, conjunctival impression cytology with goblet cell (GCs) count, symptom intensity evaluation with VAS (Visual Analogue Scale) technique were performed and compared at endpoint versus baseline.

Results: At endpoint versus baseline, respectively, variables significantly improved (Wilcoxon test, p always < 0.01). Data are expressed as median (min-max values) [CI 95%]). Tear osmolarity (mOsm/L): 290 (279-301) [286-290] versus 307 (293-315) [300-312]; OSDI score: 16 (16-26) [16-19.4] versus 28 (18-36) [24-30]; VAS score: 2.8 (1.5-3.5) [2.1-2.9] versus 5.9 (5.2-7.1) [5.6-6.1]; TFBUT (sec): 9.5 (8-12) [8.5-10.7] versus 7.1 (5.4-9) [5.6-7.8]; vital staining showed complete epithelial healing at endpoint in 48 out of 60 eyes; imprint cytology score: 1 (1-2) [1-1.2] versus 1.5 (1-2.5) [1-1.5]; GC density improved at endpoint (media ± SD: 182.6 ± 28.6 cells/mm²) as compared to baseline (142.5 ± 25.6 cells/mm², p < 0.01). Tolerability was high, with no adverse events noted.

Conclusions: A two-month treatment with Isomar Eyes plus, containing L-Carnitine, Erythrol and Betaine as osmoprotectants, is able to reduce tear osmolarity, subjective symptoms of discomfort and ocular surface epithelial damage, associated to an increasing tear film stability.

Introduction

Increasing evidence suggests that osmotic stress, caused by altered extracellular osmolality, is a highly relevant challenge to normal cell function in a variety of tissues, including human bronchial epithelial cells [1,2], peripheral blood mononuclear cells [3], kidney [4], and the corneal epithelium [5]. Dry eye disease (DED) is a “multifactorial disease of the tears and ocular surface that results in symptoms of discomfort, visual disturbance, and tear film instability with potential damage to the ocular surface. It is accompanied by increased osmolarity of the tear film and inflammation of the ocular surface” [6]. The pathophysiology of DED is referred as a vicious circle where tear hyperosmolality plays a key role [7]. Tear hyperosmolality stimulates death of the epithelial surface cells and a cascade of inflammatory events, which lead to loss of mucin-producing goblet cells. This exacerbates the tear film instability and contributes to the circle of events that perpetuate DED [8]. Both in vitro and in vivo experiments have linked hyperosmolality to inflammatory changes in DED [9,10].

Various therapies are addressed to reduce hyperosmolality in DED. Traditional approaches include the use of hypotonic tear substitutes, which shows a limited stay for a few minutes after instillation [11]. Treatments may also benefit from inclusion of osmoprotectants in the tear substitute formulation; these are naturally occurring compatible solutes that are internalized by cells, restoring cell volume and stabilizing proteins. Recent formulations of artificial tears including one or more osmoprotectants have been developed. The osmoprotective effects of L-Carnitine, betaine, and glyceral have been previously shown in osmotically stressed bacteria and yeast [12-15]. In particular, betaine is one of the essential osmolytes accumulated in most tissues to assist cell volume regulation [16-20]. It has been reported that addition of betaine to cultured human corneal epithelial cells subjected to hyperosmolar media inhibited the hyperosmotic-induced phosphorylation ratios of Jun-N-terminal and p38 kinases to below the ratios found for physiologic osmolality, indicating an osmo protective role for betaine in these cells [21]. Garrett and collaborators demonstrated the ability of exogenous betaine to stabilize human corneal limbal epithelial (HCLE) cell volume under hyperosmotic stress and to limit hyperosmotic stress-induced HCLE apoptosis, thus aiding the survival of HCLE cells under hyperosmotic stress [22].

The purpose of this study is to preliminarily investigate whether the application of a novel product containing L-Carnitine, erythrol and betaine as osmoprotectant soluble molecules designed to reduce the tear hyperosmolarity can modify signs, symptoms and tear osmolarity in dry eye patients.

Methods

This was a prospective, open-label, single-centre study performed at one research site in Bologna, Italy (Ophthalmic Unit, University of Bologna, S. Orsola-Malpighi Hospital).

Thirty patients (sixty eyes) affected by mild-moderate hyper evaporative DED with subjective ocular discomfort symptoms for over three months were enrolled (24 women, 6 men, median age 45.5 years, min-max value 24-53 yrs, 95% CI 42.3-51 yrs). The study was approved by the local Independent Ethics Committee and was conducted in accordance with the ethical principles of the Declaration of Helsinki and in agreement with the current legislation on clinical research in Italy. All subjects signed an informed consent form before starting the study.

Inclusion criteria were: age ≥ 18 years, good general health, ocular discomfort symptoms for over three months, Ocular Surface Disease Index (OSDI) [23] score ranging from 18 to 36, Schirmer test > 10 mm/5 min, TIBUT < 10 sec, corneal fluorescein staining ranging from 1 to 7 according to NEI level [24].

Exclusion criteria were: previous ocular surgery performed in the year leading up to the visit; wearing contact lenses; punctal plug placement or cauterezation, ocular allergy, concomitant topic medications. Subjects who met the inclusion criteria of the study were dispensed sodium chloride-based eye drops, to be used in both eyes for two days (wash-out period). This served to normalize the study population to an identical regimen of eye drops use, and allowed for washout and minimization of any effect from previous lubricant eye drops/medications use.

Treatment

ISOMAR Eyes Plus is an ophthalmic solution hypotonic as compared to natural tears (290 mOsm / L). The product contains 0.25% Hyaluronic Acid (HA), at a molecular weight 1.5-1.8 kD and Hypromellose 0.25%, both substances that give rise to mucus mimetic solutions and muco adhesive, with excellent lubricating properties [25]. The viscosity of such solutions is close to the non-Newtonian fluid behavior of natural tears and is such as to allow an effective moisturizing effect and a stabilization of the tear film. The Polyethylene glycol 0.25% enhances the rheological behavior of HA and its better distribution on the corneal surface. A group of osmoprotectant substances (L-Carnitine, Erythritol) are combined with Betaine, and in this respect the formulation is unique. These substances tested in vitro individually and in combination have proved to exert a protective effect against the hyperosmotic stress [26]. To complete soothing action, extracts of medicinal plants (Cineraria Maritima, Calendula, Euphrasia, Strawflower, Cornflower), known for the refreshing effect on the mucous membranes and epithelia, have been added.

Visits

The study included four visits during two months, i.e., visit 0 (V0, recruitment), after 1-3 days of wash out with sodium chloride eye drops (baseline, V1, beginning of treatment), after 1 month (V2) and after 2 months of therapy (endpoint, V3). Patients were instructed to administer one Isomar Plus drop/eye/3 times/day and to record any specific sensation at instillation.

Tests

The following tests were performed at all four visits. Subjective symptoms of dry eye were graded on the basis of the OSDI (Ocular Surface Disease Index) dry eye discomfort symptoms questionnaire. Factor analysis disclosed that there were 3 subscales, interpreted as subscale A. ocular symptoms (5 questions); subscale B. Vision-related function (4 questions); and subscale C. environmental triggers (3 questions). Each of the three subscale score was calculated and included in the statistic.

A 100 mm horizontal VAS (Visual Analogue Scale) technique was used to measure symptom intensity. Patients were asked to mark the level of their discomfort on a 100 mm, non-hatched VAS scale marked at one end as "no pain" and at the other as "pain as bad as it could be". Using a ruler, the score was determined by measuring the distance between the "no pain" end and the patient's mark, providing a range of scores from 0–100 with a higher score indicating a greater pain intensity [27].

Tear Film Break Up Time (TIBUT) was measured and recorded (average of three measurements) using 2 μL sodium fluorescein (Fluoralfa 0.25%, Alfa Intes, Italy). Schirmer test I was performed by using validated sterile test strips (ContaCare Ophthalmics and Diagnostics, Gujarat, India), as recommended in DEWS [28]. To quantify corneal and conjunctival surface damage, 1% fluorescein sodium vital staining (2 μl volume) was graded according to the NEI (0-15) [24] with the aid of a 7503 Boston yellow filter kit (equivalent to Kodak Wratten 12) to enhance staining details. Conjunctiva Van Bijsterveld score 0-18 was graded according to Lemp [24].

The following tests were performed at visits V1 and V3. Tear osmolarity was measured with the TearLab Osmolarity System (TearLab Corp, San Diego, CA, USA) at the lower external fornix, as described elsewhere, with the 305 mOsm/L value taken as cut-off for DED diagnosis [29]. Only the higher value among the two eyes was included in the statistical analysis.

Impression cytology was used to evaluate conjunctival epithelial metaplasia and goblet cells (GCs) density. Conjunctival epithelial metaplasia scoring was performed accordingly to DEWS recommendations and scored grading 0-5, as described by Tseng [30], with values > 1 being considered pathological. PAS-positive goblet cells density was expressed as the number of cells/mm² (mean of four adjacent visual fields at ×100 magnification) [31].

Patient's satisfaction was evaluated by a VAS-based satisfaction questionnaire composed by 4 questions (Table 1). For statistical analysis, score at baseline (V1) concerning their feeling about the last therapy administered prior to the study was compared to endpoint (V3).

Tolerability was assessed by a VAS scoring of specific symptoms (blurring, redness, itching, stinging) recorded upon instillation.

Statistical analysis

Data were collected in both eyes, with the worse of the two being the more relevant number included in the statistic Data were statistically analysed using the MedCalc 5.0 and SPSS 14 software and applying the Wilcoxon's test for paired to evaluate the changes between baseline and endpoint (p < 0.05 was considered to be statistically significant). Descriptive statistics for tests and variables analysed in subjects were reported as the mean ± SD. Pearson's (r) or Spearman's (ρ) correlation coefficients were applied when appropriate; correlations were considered statistically significant at p < 0.05 (small correlation strength 0.10 to 0.29; medium 0.30 to 0.49; large 0.50 to 1.00).

Results

All subjects enrolled for treatment completed the study. They declared to have administered the eye drops three times / day as requested in the protocol. No significant changes in any of the tests performed were observed between enrolment (V0) and baseline visits (V1), data from visit V0 were however included in graphs.

Subjects underwent to a progressive and statistically significant reduction of discomfort symptoms, as evaluated by OSDI score (Figure 1A); in particular, the OSDI score at endpoint was shown to be half that detected at baseline. OSDI was further analysed in the following three subscales: ocular symptoms, vision-related functions, and environmental triggers (Figure 1B). Scores on the ocular

Discussion

The present study demonstrated that treatment with a novel multiple action solution containing three osmo protectant molecules including betaine is able to reduce tear osmolarity value in mild to moderate DED patients. This was shown to be associated to an increase in tear stability, a reduction of subjective discomfort symptoms and ocular surface epithelial damage.

DED is characterized by the presence of typical symptoms of irritation, burning, itching, and sensation of a foreign body eye that significantly affect the quality of life the patients. Even in its early stages, DED subjective symptoms are accompanied by increased osmolarity of tears and reduction of mucus cells, which progresses to an advanced stage epithelial metaplasia and conjunctival pseudo-keratinization of mucosa [32]. The main mechanisms of DED are part of a vicious cycle that is self-perpetuating in the absence of adequate therapy, and can be traced back to four cornerstones referred as tear hyper osmolarity, tear instability, cell apoptosis and inflammation with release of various cytokines and MMPs.

Tear substitutes represent the first-level treatment for DED and their formulations have undergone numerous improvements to enhance their efficacy and safety to the ocular surface [33]. In vitro studies showed that some substances with osmo protectant action such as L-Carnitine, betaine, glycerol, and the polyol erythritol significantly lowered levels of activated MAP kinases in human corneal cells/mm²) as compared to baseline (V1, 142.5 ± 25.6 cells/mm², p < 0.01).

Scores for the VAS satisfaction questionnaire are summarized in table 1. Symptom relief after one month treatment and further at endpoint (V3) with respect to baseline (V1) was found. The V1 point showed the answers given by patients at baseline, which refer to their feeling about the last topical therapy administered before the present study.

The overall incidence of treatment-related Adverse Events (AEs) was very low and feelings were disappearing within 3 minutes from instillation. Mild eye irritation with conjunctival hyperemia was reported in 1 subjects, blurred vision was reported in another subject. The rate of discontinuations due to AEs was 0%.

Conjunctival impression cytology showed a statistically significant increase in GC density at endpoint (V3, media ± SD: 182.6 ± 28.6 cells/mm²) as compared to baseline (V1, 142.5 ± 25.6 cells/mm², p < 0.01).

A strong direct correlation between tear osmolarity and VAS score of subjective symptom of discomfort was shown either at baseline and endpoint (respectively Spearman's ρ = 0.610 and 0.629, p < 0.01).

Conjunctival epithelial metaplasia score significantly decreased to 0.8 ± 0.3 at endpoint (V3) with respect to baseline (V1, 1.4 ± 0.5). Conjunctival impression cytology showed a statistically significant increase in GC density at endpoint (V3, media ± SD: 182.6 ± 28.6 cells/mm²) as compared to baseline (V1, 142.5 ± 25.6 cells/mm², p < 0.01).

In figure 2 results from clinical tests were summarized. Statistically significant decrease in tear osmolarity was found at endpoint versus baseline (Figure 2A). Statistically significant improvement of TFBUT from baseline were observed at each follow-up visit and endpoint (Figure 2B) whereas Schirmer I test did not show significant changes in tear production from baseline at each follow-up visit and endpoint (Figure 2C). Corneal staining scores (Figure 2D) and conjunctival staining scores (Figure 2E) were significantly decreased from baseline at each follow-up visit and endpoint.

Figure 1: Results from Ocular Surface Disease Index (A) and VAS score (C) for subjective symptoms, recorded at enrollment (V0), baseline (V1) and after one (V2) and two (endpoint, V3) months of treatment with Isomar Eyes Plus. OSDI sub scores graphed in B refer to ocular symptoms questions (sub scale A), vision-related function questions (sub scale B) and environmental trigger questions (sub scale C). Indicate statistically significant results p < 0.05.
cells subjected to hyperosmolar stress condition that simulate the DED [21]. Interestingly, these osmo protectants not only suppressed production but also inhibited activation of MMP-9 and MMP-2, and L-Carnitine showed the strongest suppressive effect on these MMPs [34]. L- Carnitine was also shown to regulate cell volume under hyperosmotic stress in vitro models and ameliorate hyperosmotic stress–induced apoptosis evaluated with TNF-alpha release and caspase enzymes activity [35]. Betaine was shown to exert similar protective effects against apoptosis [22]. Further, osmoprotectant L-Carnitine, erythrol and betaine were shown to suppress inflammatory responses in HCECs exposed to hyperosmotic stress, with particular reference to pro-inflammatory cytokines, TNF-α, IL-1β and IL-6, and chemokines, IL-8, CCL2 and CCL20, thus providing evidence on potential efficacy in reducing innate inflammation in DED [36]. Efficacy of osmo protectants betaine, L-Carnitine and erythrol was also confirmed in environmentally induced DED animal models. Treatment of mouse dry eye with osmo protectants resulted in a significant reduction in corneal staining, number of apoptotic epithelial cells, and expression of TNF-α, IL-17, IL-6, or IL-1β, as well as significantly increase of conjunctival goblet cells density [26].

L-Carnitine and erythrol enter in formulations of commercially available tear substitutes and the efficacy of these products has been evaluated in the course of clinical trials.

Kaercher and coll performed observational studies in large populations of DED patients and found a reduction in subjective symptoms of discomfort and improvement of tear stability after 4 weeks treatment with products containing osmo protectants L/ Carnitine and erythrol [37,38]. Subjective symptom reduction and improvement of tear stability were confirmed in another multi centre study after three months of therapy with the same commercially available products containing osmo protectant L-Carnitine and erythrol [39]. On the contrary, Lanzini and coll found no significant difference in Schirmer I Test, TFBUT and vital staining but significant reduction of the expression of MMP-9 and IL6 associated to a better in vivo confocal microscopy ocular surface morphology in an osmo protectant containing product treated group compared to a non-osmo protectant product treated control group of DED patients [40].

All patients enrolled in the present study exhibited good

**Figure 2**: Summary of results from Tear Osmolarity (A), Tear Film Break Up Time (B), Schirmer I test (C), corneal vital staining scored with the NEI (National Eye Institute) score (D) and conjunctival vital staining scored with the van Bisterveldt score (E) recorded at enrollment (V0), baseline (V1) and after one (V2) and two (endpoint, V3) months of treatment with Isomar Eyes Plus. Indicate statistically significant results p < 0.05.
compliance to the treatment: data showed good tolerability, lacking of adverse effects upon instillation and high satisfaction score. All patients reported a statistically significant reduction in subjective symptoms of discomfort, conjunctival epithelial metaplasia (associated to increase of GC density) and tear osmolality values, both after one month treatment and at endpoint by comparison with baseline. A strong direct correlation was found between DED symptoms scored with VAS scale and tear osmolality values, in agreement with previous works [41,42], and further confirming the role of tear hyperosmolality in epithelial damage [9,43].

Our results showed statistically significant increasing in TFBUT in all patients, improving over time, although only 21 out of 30 patients was able to reach normal values over the period of observation in this study. Both corneal and conjunctival epithelial damage were significantly reduced after one month of treatment and vital staining showed complete epithelial healing at endpoint in 48 out of 60 eyes.

In summary, our study demonstrated that a two-month treatment in mild to moderate dry eye patients with isomor eyes plus, containing L-Carnitine, Erythrol and Betaine as osmoprotectants, is able to reduce tear osmolality, subjective symptoms and ocular surface epithelial damage, associated to an increasing tear film stability.
