Abstract
Bechet’s disease is a multisystemic process that can mimic many other diseases. Neurological features can be its first-onset symptoms. Brainstem is usually affected, so that a wide differential diagnosis is mandatory. We report the case of a patient who developed a fulminant and rapidly progressive brainstem encephalitis owing to NeuroBechet’s disease.

Keywords
Bechet, Encephalitis, Facial Palsy, Pons, Magnetic Resonance Image, Uveitis

Introduction
Bechet’s disease (BD) is a hard-to-diagnose entity. Neurological features can sometimes be the first manifestation of the disease. Its symptoms can be so different, so that a wide differential diagnosis with many neurologic or systemic processes is mandatory. Systemic features can be quite helpful. We report the case of a patient who developed fulminant progressive brainstem encephalitis as onset of Neuro-Bechet’s disease. A review of the literature is made also.

Case Description
A sixty-nine year old male was referred to Emergency Room (ER) in our Hospital. He had antecedents of mild blood hypertension and left facial palsy four years ago. He complained of acute right facial weakness for the last two days. There was no evidence of infectious disease or recent vaccinations. Subsequently, he developed dizziness, nausea and vomiting. At physical examination, right facial palsy was detected. In addition, we found right abducens paresis, right hypoacusis and horizontal left nystagmus.

Blood sample tests requested (ANAS, ANCAS, ACE, Antiphospholipid antibodies, onconeural antibodies, AntiNMO and AntiGQ1b antibodies, RPR, TPHA, HIV and viruses tests) were normal or negative. X-ray chest and Body-CT showed no abnormalities. Brain MRI (Figure 1) showed a high-T2 signal lesion at pons and pontomedullary junction, affecting middle cerebellar peduncles also. MR-spectroscopy showed no evidence of tumoral processes.

An empiric treatment with high-dose steroids was started. The patient improved clinically. So did a new MRI. Nevertheless, his condition worsened after a few weeks, developing painful ulcers and papular lesions on the right forearm.

A new MRI was requested. Worsening of the previous lesions with increased enhancement, mesencephalic and cerebellar edema (crushing the fourth ventricle) were also present (Figure 2). A PET exam showed no evidence of malignancy. A brainstem biopsy was rejected by the reference center of neurosurgery. Skin biopsy showed a palisading neutrophilic granulomatous dermatitis.

Conclusions

BD is a systemic inflammatory disorder. Painful
and recurrent buco-genital ulcers are the hallmark, although skin lesions, uveitis, vascular events or gastrointestinal disorders can appear also. In rare occasions it can spread to heart, lungs, kidney or peripheral nervous system even.

Young male use to be affected, especially in countries related to the Old Ancient Silk Route. Frequency rates in NB can be quite variable (3-44% of the patients).

Neurologic disturbances in BD can be classified in two main groups [1]. Parenchymal (meaning 20-60% of the cases) and non-parenchymal processes (see Table 1). According to literature, brain white matter, brainstem, thalamus and basal ganglia are often impaired.

Clinical disturbances are related to the localization of the lesions [3]. So that, differential diagnosis can sometimes be difficult, especially with Multiple Sclerosis (MS). Sensitivity impairment, optic neuritis, internuclear ophthalmoplegia, limb ataxia or cerebellar dysarthria are more frequent in patient with MS. On the other hand, headache, pseudobulbar speech and cognitive disturbances are more frequent in patients with NB. Other processes like Primary Nervous Central System Lymphoma (PNCSL) need to be excluded [4].

MRI is a fundamental key for NB diagnosis [5]. High-T2 brain signals are found. They usually appear at brain peduncle and pons junction a sugerenent feature, pontomedullary junction, thalamic/hypothalamic areas, basal ganglia and cerebellum. On the other hand, subcortical and periventricular areas are not often impaired [6]. In NB, confluent lesions spreading

Vasculitis is the manifest cause of death. It can affect any caliber and location vessels. Venous impairment happens more often. Brain or kidney arteries are rarely impaired. BD debuts with vascular events in less than 25% of the cases, mimicking acute strokes. There are a few cases of patients with NB developing brain hemorrhages without aneurisms or previous vascular abnormalities. Blood Hypertension or hemorrhagic diathesis are the manifest risk factors. Intracranial vasculitis \[9,10\] can also be another risk factor, although quite unusual (our patient had it).

Concerning therapy, high steroid doses are advocated. Immunosuppressive treatment is considered in severe parenchymal forms. First-line agents include Azathioprine, Methotrexate or Cyclophosphamide. Alpha-Interferon, Infliximab or etanercept are required if first line treatment fails or is not well tolerated.

to thalamus and basal ganglia (the so-called “brainstem plus sign”) is \[7\]. Other diseases like SLE rarely affect the brainstem.

CSF analysis can show abnormalities in 60-80% of the patients. Mild pleocytosis and raised proteins levels are the most frequent findings, although not specific.

NB Diagnostic criteria \[3\] were reported in 2013 after an expert meeting (see Tables 2 and Table 3).

Neural biopsy or other histopathologic evidences are not regularly needed, but in atypical cases or exceptional ones like this.

Disease’s course is unpredictable, related to the onset clinical features. Worse prognosis is frequently seen in subacute, rapidly progressive cases. Ataxia, bladder incontinence, confusion and less survival are frequently seen in these patients.
We report the case of a patient with an atypical, refractory and rapidly progressive form of NB, who developed an exceptional complication (pontine hemorrhagic stroke) due to brain angiitis. Necropsy findings supported our clinical diagnosis.

Acknowledgments

We would really like to thank Dr. Angel Fernández Flórez for his contribution to the diagnosis of the patient and for providing the pathological and necropsy images.

Conflict of Interests

No funds have been received for this work. All the authors deny conflict of interests.
